

## Problem 4

### I.

Answer the following questions on logic circuits. Let us design a 2-bit comparator (CMP) that takes 2-bit positive input values  $A = a_2a_1$  and  $B = b_2b_1$ . The CMP outputs  $c$ , where  $c$  is 1 when  $A \geq B$ , and 0 otherwise. The symbol of the 2-bit CMP is shown in Fig. 1.

- (1) Write the truth table of the 1-bit comparator  $CMP_1$  that outputs  $c_1$  as shown below, where  $a_1$  and  $b_1$  are the input values.

$$c_1 = \begin{cases} 1, & a_1 \geq b_1 \\ 0, & a_1 < b_1 \end{cases}$$

- (2) Write the truth table of the 1-bit comparator  $CMP_2$  that outputs  $c_2$  as shown below, where  $a_2$ ,  $b_2$ , and  $c_1$  are the input values. Note that  $c_1$  is the output described in Question (1).

$$c_2 = \begin{cases} 1, & a_2 > b_2 \\ c_1, & a_2 = b_2 \\ 0, & a_2 < b_2 \end{cases}$$

- (3) You can design the 2-bit CMP by combining the circuits of  $CMP_1$  and  $CMP_2$ , described in Questions (1) and (2). Draw a circuit of the 2-bit CMP using the symbols shown in Fig. 2.

Next, let us design a sequential circuit MAX using the 2-bit CMP. When 2-bit positive values  $X_1, X_2, \dots$  are input sequentially, the MAX outputs the maximum value of the inputs. Design the MAX according to the following procedure.

- (4) Using the 2-bit CMP and a 2-bit D flip-flop (D-FF), design a circuit which stores  $\max(A, B)$  in the 2-bit D-FF. Draw the circuit using the symbols shown in Figs. 1, 2, and 3.
- (5) You can construct the sequential circuit MAX by assigning  $X_i$  to the input  $A$ , and  $\max(X_1, X_2, \dots, X_{i-1})$  to the input  $B$  of the circuit designed in Question (4). Draw the sequential circuit MAX using the symbols shown in Figs. 1, 2 and 3. You can assume that the initial input value of  $B$  is 00.

## II.

Answer the following questions on storage and management of data using hash tables. Let us consider a method of managing positive integers in a hash table `table[N]` with  $N$  elements. Here, a hash function  $H(x) = \text{mod}(x, N)$  is used to indicate the index to store a positive integer  $x$  in the hash table. When positive integers have the same hash value, they are managed by the linked list of data structure node which is described in Program 1.

- (1) Show the contents of `table[N]`, when  $N = 11$  and integers  $\{15, 53, 22, 59, 15, 41, 20\}$  are stored using the hash function in sequence.
- (2) Program 2 describes `insert(x)` function that stores positive integer  $x$  in `table[N]`. Fill in the blanks of Program 2 to complete the program in C language.
- (3) Assume that `search(x)` function returns 1 if a given positive integer  $x$  is stored in `table[N]`, and it returns 0 otherwise. Write the `search(x)` function in C language.
- (4) Describe in a few lines the point(s) to pay attention to, when you write a function that deletes a positive integer  $x$  stored in `table[N]`.

```

/* Program 1 */
struct node {
    int value;
    struct node *next;
};
struct node *table[N];

/* Program 2 */
int H(int x) { return(x % N); }
void insert(int x) {
    struct node *new, *check;

    new = (struct node *)malloc(sizeof (struct node));
    new -> value = x;
    new -> next = NULL;
    check = table[H(x)];

    
}

```
